1. Clinical Image

Retinitis pigmentosa and choroidal coloboma are known to usually exist as two separate entities. The fundus photo shows features of Retinitis pigmentosa, with an isolated coloboma inferior to disc, in a 30 years old lady, who, presented with decreased peripheral vision and nyctalopia. On evaluation she was found to have 6/6 vision bilaterally. Anterior segment was unremarkable in both eyes. Right eye fundus showed features of Retinitis pigmentosa. After extensive literature review, such association of unilateral coloboma in a patient with bilateral Retinitis pigmentosa is extremely rare and has been reported only in a few cases [1,2].
